### What is a Sensitive Ecosystem?

For the purpose of this study, an ecosystem is considered to be a portion of the landscape with relatively uniform dominant vegetation.

Sensitive ecosystems are those which are fragile and/or rare, or those ecosystems which are ecologically important because of the diversity of species they support.

### Rationale

Intense development pressure fueled by population and economic growth has fragmented and degraded many terrestrial ecosystems. A high proportion of these ecosystems are now designated as at risk in BC. Sensitive ecosystems typically have high biological diversity and are a vital part of the landscape. They provide ecosystem services for a healthy economy and to promote, protect and enhance the quality of life. They regulate climate, clean water, generate and clean soils, recycle nutrients and pollinate our crops. To protect these areas, sensitive ecosystems must be located, identified and mapped. From 1993 to 1999 the Provincial and Federal Governments completed a Sensitive Ecosystems Inventory of East Vancouver Island and the Gulf Islands. This mapping project is an updated version of that product.

### Purpose

The purpose of this Sensitive Ecosystems map is to identify the location of sensitive ecosystems. The goal of this mapping exercise is to encourage informed land use decisions that will conserve sensitive ecosystems. This map and the accompanying data provide site-specific ecological information that can be used to flag sites of conservation concern, to promote land stewardship and to prompt detailed field surveys and consideration of ecological values before changes to the land are initiated.

### Data Limitations

The Sensitive Ecosystems map is a tool to alert decision makers to the existence of sensitive ecosystems. However, when land-use changes are proposed, detailed on-ground site assessments are necessary. For sites that were not field checked, the accuracy of the data depends heavily on the expertise, local knowledge, and professional judgment of the mapper and the quality and quantity of available source data. Because the area is changing rapidly, reference to the data field is used as the information source is advised.

### Methodology

Due to the mapping scale of the aerial photographs, the minimum polygon size is generally 1/4 hectare. Enlargement of the data beyond the source scale may result in unacceptable distortion and faulty registration with other data sets.

### What can be done to protect the sensitive ecosystems?

Direct and indirect impacts to these ecosystems can be avoided by:

- Retaining or creating vegetated buffers around sensitive ecosystems to isolate them from outside disturbances;
- Controlling land and water access to fragile ecosystems;
- Controlling invasive species;
- Allowing natural disturbances to occur;
- Maintaining water quality.

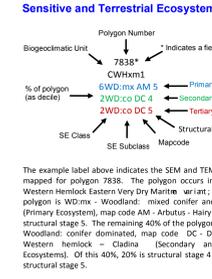

### If development must occur, develop carefully!

Conduct an ecological inventory to identify the existing flora and fauna and to locate any threatened or endangered plant and animal species, plant communities, and habitat features needing protection.

Plan and implement all development activities in a manner that will not adversely affect or disturb the sensitive ecosystem. Consult a qualified professional to interpret the ecological inventory data and work to incorporate designs that maintain the functions and values of the natural ecosystem.

UTM Projection Zone 10 NAD83

## Sensitive Ecosystems

Sensitive ecosystems are fragile and/or rare, or are ecologically important because of the diversity of species they support.

Ecosystem Type	Primary Ecosystem	Secondary	Tertiary
<b>Old Forest (OF):</b>	Primary Ecosystem	Secondary	Tertiary
<b>Definition:</b>	Conifer-dominated dry to moist forest types, structural stage 7, generally >250yrs.		
<b>Importance:</b>	Due to the lack of disturbance, old forest ecosystems are often associated with rich communities of plants and animals that may be dependent upon the unique environmental conditions created by these forests.		
<b>Subclasses:</b>	<ul style="list-style-type: none"> <li>co (conifer-dominated) - greater than 75% coniferous species</li> <li>mc (mixed conifer and deciduous) - forest dominated with a mixture of coniferous and broadleaf trees (&lt;75% coniferous and &gt;25% broadleaf)</li> </ul>		
<b>Woodland (WD):</b>	Primary Ecosystem	Secondary	Tertiary
<b>Definition:</b>	Dry open forests, generally between 10 and 30% tree cover, can be conifer-dominated or mixed conifer and arbutus stands; because of open canopy, will include non-forested openings, often with shallow soils and bedrock outcroppings.		
<b>Importance:</b>	Woodlands are nationally, provincially and regionally rare and highly fragmented. A rich assemblage of plants, insects, reptiles and birds are often to these ecosystems due to the food sources, habitat and proximity to the ocean. Garry oak woodlands, for example support the highest plant species diversity of any terrestrial ecosystem in British Columbia and are especially vulnerable to rural development.		
<b>Subclasses:</b>	<ul style="list-style-type: none"> <li>bd (broadleaf) - dominant broadleaf with &lt;15% coniferous species</li> <li>mx (mixed conifer and deciduous) - mixed conifer and broadleaf with a minimum of 25% cover of either group is included in the total tree cover</li> </ul>		
<b>Herbaceous (HB):</b>	Primary Ecosystem	Secondary	Tertiary
<b>Definition:</b>	Non-forested ecosystems (less than 10% tree cover), generally with shallow soils. They include bedrock outcroppings, large openings within forested areas, spits, dunes and shorelines vegetated with grasses and herbs.		
<b>Importance:</b>	Terrestrial Herbaceous ecosystems are characterized by thin soils which are easily disturbed. Herbaceous plants can be easily trampled or dislodged onto bare soil where they cannot re-establish. Thus they are highly vulnerable to a range of human disturbance factors including residential development and various recreational uses.		
<b>Subclasses:</b>	<ul style="list-style-type: none"> <li>hb (herbaceous) - non-forested, less than 10% tree cover, generally shallow soils, often with exposed bedrock, predominantly a mix of grasses and forbs, also lichens and mosses</li> <li>cc (coastal herbaceous) - rocky shoreline or islet, influenced by the marine environment and characterized by less than 20% vegetation cover of grasses, forbs, mosses and lichens</li> <li>sp (spit) - finger-like extension of beach, composed of sand or gravel deposited by longshore drifting; low to moderate cover of salt-tolerant grasses and forbs</li> <li>ds (dunes) - ridge or hill, or beach area created by windblown sand; may be more or less vegetated depending on depositional activity, beach dunes will have low cover of salt-tolerant grasses and forbs</li> <li>rb (rock) - &gt;25% of total vegetation cover is shrub cover, with grasses and forbs</li> <li>ro (rock) - rock outcrops not dominated by shrubs</li> </ul>		
<b>Riparian (RI):</b>	Primary Ecosystem	Secondary	Tertiary
<b>Definition:</b>	Areas adjacent to water bodies (rivers, lakes, ocean, wetlands) which are influenced by factors such as erosion, sedimentation, flooding and/or subterranean irrigation due to proximity to the water body. Structural stages 1 - 7.		
<b>Importance:</b>	Riparian ecosystems support a disproportionately high number of vascular plant, moss, amphibian and small mammal species for the area they occupy.		
<b>Subclasses:</b>	<ul style="list-style-type: none"> <li>fl (low bench floodplain) - flooded at least every other year for moderate periods of growing season; plant species adapted to extended flooding and erosion, low or tall shrubs most common</li> <li>mb (medium bench floodplain) - flooded every 1-3 years for short periods (10-25 days); deciduous or mixed forest dominated by species tolerant of flooding and periodic sedimentation, trees occur on elevated microsites</li> <li>rh (high bench floodplain) - only periodically and briefly inundated by high waters, but lengthy submergence flow in the flooding zone, typically conifer-dominated floodplains of larger coastal rivers</li> <li>rl (river) - narrow linear communities along with open water bodies (rivers, lakes and ponds) where there is no floodplain, irregular flooding</li> <li>gl (gully channel) - watercourse in which a steep slope is exposed only</li> <li>rl (river) - watercourse is large enough to represent &gt;10% of the polygon</li> <li>sh (shrub) - shrub-dominated floodplain or lakeshore</li> </ul>		
<b>Wetland (WN):</b>	Primary Ecosystem	Secondary	Tertiary
<b>Definition:</b>	Areas that are saturated or inundated with water for long enough periods of time to develop vegetation. This may result from flooding, fluctuating water tables, tidal influences or poor drainage conditions.		
<b>Importance:</b>	Wetland ecosystems are sensitive and important because they exhibit rarity, high biodiversity, highly specialized habitat, specialized functions and connectivity.		
<b>Subclasses:</b>	<ul style="list-style-type: none"> <li>bg (bog) - nutrient poor wetland, on organic soils (sphagnum peat), water source predominantly from precipitation; may be tree or shrub dominated</li> <li>ds (dry) - water medium wetland (sedge peat</li></ul>
